DESA

The Department of Economic and Social Affairs of the United Nations Secretariat is a vital interface between global policies in the economic, social and environmental spheres and national action. The Department works in three main interlinked areas: (i) it compiles, generates and analyses a wide range of economic, social and environmental data and information on which States Members of the United Nations draw to review common problems and take stock of policy options; (ii) it facilitates the negotiations of Member States in many intergovernmental bodies on joint courses of action to address ongoing or emerging global challenges; and (iii) it advises interested Governments on the ways and means of translating policy frameworks developed in United Nations conferences and summits into programmes at the country level and, through technical assistance, helps build national capacities.

Note

The designations employed in this report and the material presented in it do not imply the expression of any opinion whatsoever on the part of the Secretariat of the United Nations concerning the legal status of any country, territory, city or area or of its authorities, or concerning the delimitation of its frontiers or boundaries.

Symbols of United Nations documents are composed of capital letters combined with figures.

This publication has been issued without formal editing.

PREFACE

This report presents the highlights of the results of the *2010 Revision* of the official United Nations population estimates and projections prepared by the Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat. The *2010 Revision* constitutes the twenty second round of the global population estimates and projections produced by the Population Division since 1951.

The *2010 Revision* breaks new ground in the production of population projections. It is the first standard *Revision* to include projections up to 2100 for all countries and areas of the world. Previous *Revisions* presented country projections only for the period ending in 2050. In order to extend the projection period to 2100, a new method for the projection of fertility had to be developed. The method used in the *2010 Revision* is based on the advances made in projecting fertility since the *2000 Revision*, advances that have been combined with a probabilistic approach to yield the future paths of fertility used in producing the medium variant of the *2010 Revision*. The standard output of the *2010 Revision* does not, however, include fully probabilistic projections. The standard output of the *2010 Revision* includes only the usual projection variants and scenarios included in other *Revisions* of *World Population Prospects*.

The full results of the *2010 Revision* are presented in two volumes. The first volume provides comprehensive tables displaying key demographic indicators for each development group, major area, region and country for selected periods or dates within 1950-2100. The second volume contains demographic profiles presenting time series and plots covering the period from 1950 to 2100 for selected indicators for each country with at least 100,000 inhabitants in 2010 as well as for development groups, major areas and regions. This volume provides, for each country and area, a brief description of the data sources and demographic methods used to make the base-year estimates for each country or area. Key findings of the 2010 Revision are also included in each volume together with the projections assumptions, and a wall chart provides summary indicators for the most recent period.

The detailed results of the *2010 Revision* are made available through a variety of media. The Population Division's website provides access to the comprehensive data organized in Excel files as well as to an interactive database allowing the user to obtain specific information on a few countries at a time. The website can be accessed at www.unpopulation.org. Users requiring the complete results of the *2010 Revision* can purchase them on CD-ROM. A description of the data contained in the different CD-ROMs available and an order form are posted on the Population Division's web site.

Responsibility for the *2010 Revision* rests with the Population Division. In preparing the *2010 Revision*, the Population Division relied on the collaboration of the regional commissions, especially the Economic Commission for Latin America and the Caribbean, and that of UNAIDS, the specialized agencies and other relevant bodies of the United Nations system. The Statistics Division of the Department of Economic and Social Affairs of the United Nations Secretariat, through its *United Nations Demographic Yearbook* and its accompanying databases, provided access to official national population statistics used in the preparation of the *2010 Revision*. The Population Division is grateful for the contributions made by all these entities.

For further information about the *2010 Revision*, please contact Ms. Hania Zlotnik, Director, Population Division, United Nations, New York, NY 10017, USA (Fax: 1 212 963 2147).

EXPLANATORY NOTES

The following symbols have been used in the tables throughout this report:

Two dots (..) indicate that data are not available or are not reported separately.

A hyphen (-) indicates that the item is not applicable.

A minus sign (-) before a figure indicates a decrease.

A full stop (.) is used to indicate decimals.

Years given refer to 1 July.

Use of a hyphen (-) between years, for example, 1995-2000, signifies the full period involved, from 1 July of the first year to 1 July of the second year.

Numbers and percentages in tables do not necessarily add to totals because of rounding.

References to countries, territories and areas:

The designations employed and the material in this publication do not imply the expression of any opinion whatsoever on the part of the Secretariat of the United Nations concerning the legal status of any country, territory or area or its authorities, or concerning the delimitation of its frontiers or boundaries.

The designation “more developed” and “less developed” regions are intended for statistical purposes and do not express a judgment about the stage reached by a particular country or area in the development process. The term “country” as used in this publication also refers, as appropriate, to territories or areas.

More developed regions comprise all regions of Europe plus Northern America, Australia/New Zealand and Japan. Less developed regions comprise all regions of Africa, Asia (excluding Japan), and Latin America and the Caribbean as well as Melanesia, Micronesia and Polynesia. Countries or areas in the more developed regions are designated as “developed countries”. Countries or areas in the less developed regions are designated as “developing countries”.

The least developed countries, as defined by the United Nations General Assembly in its resolutions (59/209, 59/210, 60/33, 62/97, 64/L.55) include 48 countries in 2011: 33 in Africa, 9 in Asia, 5 in Oceania and one in Latin America and the Caribbean. Those 48 countries are: Afghanistan, Angola, Bangladesh, Benin, Bhutan, Burkina Faso, Burundi, Cambodia, Central African Republic, Chad, Comoros, Democratic Republic of the Congo, Djibouti, Equatorial Guinea, Eritrea, Ethiopia, Gambia, Guinea, Guinea-Bissau, Haiti, Kiribati, Lao People's Democratic Republic, Lesotho, Liberia, Madagascar, Malawi, Mali, Mauritania, Mozambique, Myanmar, Nepal, Niger, Rwanda, Samoa, São Tomé and Príncipe, Senegal, Sierra Leone, Solomon Islands, Somalia, Sudan, Timor-Leste, Togo, Tuvalu, Uganda, United Republic of Tanzania, Vanuatu, Yemen and Zambia. These countries are also included in the less developed regions.

The group denominated “other less developed countries” comprises all countries in the less developed regions minus the least developed countries.

The term “sub-Saharan Africa” is used to designate the countries in Africa that exclude those in Northern Africa but include Sudan.

Countries and areas are grouped geographically into six major areas designated as: Africa; Asia; Europe; Latin America and the Caribbean; Northern America, and Oceania. These major areas are further divided into 21 geographical regions.

The names and composition of geographical areas follow those presented in “Standard country or area codes for statistical use” (ST/ESA/STAT/SER.M/49/Rev.3), available at <http://unstats.un.org/unsd/methods/m49/m49.htm>.

The following abbreviations have been used:

AIDS	Acquired immunodeficiency syndrome
ART	Antiretroviral therapy
DESA	Department of Economic and Social Affairs
HIV	Human immunodeficiency virus
MDGs	Millennium Development Goals
SAR	Special Administrative Region
UNAIDS	Joint United Nations Programme on HIV/AIDS

CLASSIFICATION OF COUNTRIES BY MAJOR AREA AND REGION OF THE WORLD

Africa			
<i>Eastern Africa</i>	<i>Middle Africa</i>	<i>Northern Africa</i>	<i>Western Africa</i>
Burundi	Angola	Algeria	Benin
Comoros	Cameroon	Egypt	Burkina Faso
Djibouti	Central African Republic	Libyan Arab Jamahiriya	Cape Verde
Eritrea	Chad	Morocco	Côte d'Ivoire

EXECUTIVE SUMMARY

The *2010 Revision* is the twenty second round of official United Nations population estimates and projections prepared by the Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat. These are used throughout the United Nations system as the basis for activities requiring population information. The *2010 Revision* builds on the *2008 Revision* and incorporates the results of the 2000 and 2010 round of national population censuses as well as of recent specialized surveys carried around the world. These sources provide both demographic and other information to assess the progress made in achieving the internationally agreed development goals, including the Millennium Development Goals (MDGs). The comprehensive review of past worldwide demographic trends and future prospects presented in the *2010 Revision* provides the population basis for the assessment of those goals.

According to the *2010 Revision* of the official United Nations population estimates and projections, the world population is projected to reach 7 billion in late 2011, surpass 9 billion people by 2050 and exceed 10 billion in 2100 (figure 1).

Most of the additional 3 billion people from now to 2100 will enlarge the population of developing countries, which is projected to rise from 5.7 billion in 2011 to 8.0 billion in 2050 and to 8.8 billion in 2100, and will be distributed over the whole period among the population aged 15-59 (1.2 billion) and 60 or over (1.9 billion) because the number of children under age 15 in developing countries will decrease.

In contrast, the population of the more developed regions is expected to change minimally, passing from 1.24 billion in 2011 to 1.34 billion in 2100, and would have declined to 1.11 billion were it not for the projected net migration from developing to developed countries, which is projected to average 2.2 million persons annually from 2011 to 2050 and 0.8 million from 2050 to 2100.

The results of the *2010 Revision* incorporate the findings of the most recent national population censuses and of numerous specialized population surveys carried out around the world. *The 2010 Revision* provides the demographic data and indicators to assess trends at the global, regional and national levels and to calculate many other key indicators commonly used by the United Nations system.

Population in developing countries still young

Currently the population of the less developed regions is still young, with children under age 15 accounting with 29 per cent of the population and young persons aged 15 to 24 accounting for a further 18 per cent. In fact, the numbers of children and young people in the less developed regions are at an all time high (1.6 billion children and 1.0 billion young people), posing a major challenge for their countries, which are faced with the necessity of providing education or employment to large cohorts of children and youth even as the current economic and financial crisis unfolds. The situation in the least developed countries is even more pressing because children under 15 constitute 40 per cent of their population and young people account for a further 20 per cent.

In the more developed regions, children and youth account for just 17 per cent and 13 per cent of the population, respectively, and whereas the number of children is expected to change little in the future, remaining close to 218 million in 2050 and 226 in 2100; the number of young people is projected to decrease from 156 million currently to 144 million in 2050 and then slight increase to 151 million in 2100.

In both the more and the less developed regions, the number of people in the main working ages, 25 to 59, is at an all time high: 606 million and 2.5 billion, respectively. Yet, whereas in the more developed regions that number is expected to peak over the next decade and decline thereafter reaching 531 millions

in 2050 and 525 million in 2100, in the less developed regions it will continue rising, reaching 3.6 billion in 2050 and 3.7 billion in 2100 and increasing by nearly half a billion over the next decade. These population trends justify the urgency of supporting employment creation in developing countries as part of any strategy to address the global economic crisis that the world is experiencing.

Globally, population aged 60 or over is the fastest growing

Furthermore, the implications of population ageing cannot be dismissed. In the more developed regions, the population aged 60 or over is increasing at the fastest pace ever (growing at 2.4 per cent annually before 2050 and 0.7 per cent annually from 2050 to 2100) and is expected to increase by more than 50 per cent over the next four decades, rising from 274 million in 2011 to 418 million in 2050 and to 433 million in 2100. Compared with the more developed world, the population of the less developed regions is ageing rapidly. Over the next three decades, the population aged 60 or over in the developing world is projected to increase at rates far surpassing 3 per cent per year and its numbers are expected to rise from 510 million in 2011 to 1.6 billion in 2050 and to 2.4 billion in 2100.

Projected trends are contingent on fertility declines in developing countries

Population ageing results mainly from declining fertility. According to the *2010 Revision*, fertility in the less developed regions as a whole is expected to drop from 2.67 children per woman in 2005-2010 to 2.19 in 2045-2050 and to 2.02 in 2095-2100. The reduction projected for the group of 48 least developed countries is even steeper: from 4.41 children per woman to 2.76 children per woman in 2045-2050 and to 2.13 in 2095-2100. To achieve such reductions, it is essential that access to family planning expands, particularly in the least developed countries. Around 2009, the use of modern contraceptive methods in the least developed countries was a low 25 per cent among women of reproductive age who were married or in union and a further 24 per cent of those women had an unmet need for family planning. The urgency of realizing the projected reductions of fertility is brought into focus by considering that, if fertility were to remain constant at the levels estimated for 2005-2010, the population of the less developed regions would increase to 9.7 billion in 2050 and to 25.8 billion in 2100 instead of the 8.0 billion and 8.8 billion projected by assuming that fertility declines. That is, without further reductions of fertility, the world population by 2100 could increase by nearly six times as much as currently expected.

Projected growth linked to sustained progress in HIV/AIDS prevention and treatment

The projected population trends also depend on achieving a major increase in the proportion of AIDS patients who get anti-retroviral therapy to treat the disease and on the success of efforts to control the further spread of HIV.

In the *2010 Revision*, the impact of the epidemic was modeled in 48 countries where adult HIV prevalence reached 1 per cent or higher at some point during 1980-2010 or where the number of people living with HIV/AIDS was at least half a million in 2009. Among those 48 countries, 37 are in Africa and 15 had an adult HIV prevalence of at least 5 per cent in 2010.

The *2008 Revision* modeled the impact of HIV/AIDS in 58 affected countries, eleven of which have been dropped from the list of affected countries in the *2010 Revision* because their HIV prevalence was revised downward (Barbados, Brazil, Cambodia Dominican Republic, Estonia, Honduras, Mauritius, Papua New Guinea, Sudan, Trinidad and Tobago, Ukraine) and one has been added (Gambia). In projecting the effect of the disease, it has been assumed that 41 of the affected countries will manage to provide by 2015 anti-retroviral treatment to 70 per cent or more of the adult persons suffering from AIDS and that another five will reach treatment levels ranging from 50 per cent to 70 per cent by 2015. In the rest of the affected countries, treatment levels are expected to be lower, reaching between 40 per cent and 50 per cent by 2015.

However, the realization of these new projections depends on sustained funding for HIV/AIDS prevention and treatment programmes in the affected countries, funding that is highly dependent on the commitment of donor countries and needs to be maintained despite the global economic downturn.

The full results of the *2010 Revision* will be issued in a series of three volumes. A wallchart²⁸ was already published. Data on particular countries can also be accessed online at the website of the Population Division (www.unpopulation.org).

2010 Revision of World Population Prospects

Key Findings

1. In July 2011, the world population will reach 6.97 billion, 467 million more than in 2005 or a gain of 77 million persons annually. Assuming that fertility levels continue to decline, the world population is expected to reach 9.3 billion in 2050 and 10.1 billion in 2100 and to be increasing by about 35 million persons annually by 2100, according to the medium variant.
2. Future population growth is highly dependent on the path that future fertility takes. In the medium variant, fertility declines from 2.52 children per woman in 2005-2010 to 2.17 children per woman in 2045-2050. If fertility were to remain about half a child above the levels projected in the medium variant, world population would reach 10.6 billion by 2050 and 15.8 billion by 2100. A fertility path half a child below the medium would lead to a population of 8.1 billion by mid-century and 6.2 billion by the end of the century. Consequently, population growth until 2050 is inevitable even if the decline of fertility accelerates.
3. In the more developed regions, fertility has increased slightly in recent years so that its estimated level in 2005-2010, 1.66 children per woman, according to the *2010 Revision* is higher than the one reported in the *2008 Revision* (1.64 children per woman). As a result of the slightly higher projected fertility and a sustained net in-migration averaging 2.2 million annually from 2011 to 2050 and 0.8 million from 2050 to 2100, the population of the more developed regions is expected to increase slightly from 1.24 billion in 2011 to 1.31 billion in 2050 and to 1.34 billion.
4. The population of the 48 least developed countries is still the fastest growing in the world, at 2.5 per cent per year. Although its rate of increase is expected to moderate significantly over the next decades, the population of the least developed countries is projected to double, passing from 0.85 billion in 2011 to 1.7 billion in 2050 and to 2.7 billion in 2100. Growth in the rest of the developing world is also projected to be robust, though less rapid, with its population rising from 4.9 billion in 2011 to 6.3 billion 2050 and then slightly declining to 6.1 billion in 2100 according to the medium variant.
5. Slow population growth brought about by reductions in fertility leads to population ageing, that is, it produces populations where the proportion of older persons increases while that of younger persons decreases. In the more developed regions, 22 per cent of population is already aged 60 years or over and that proportion is projected to reach 32 per cent in 2050 and 33 in 2100. In developed countries as a whole, the number of older persons has already surpassed the number of children (persons under age 15), and by 2050 and 2100 the number of older persons in developed countries will be nearly twice the number of children.

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2011). *World Population Prospects: The 2010 Revision*. New York: United Nations.

6. Population ageing is less advanced in developing countries. Nevertheless, the populations of a majority of them are poised to enter a period of rapid population ageing. In developing countries as a whole, just 9 per cent of the population is today aged 60 years or over but that proportion will more than double by 2050, reaching 20 per cent that year, and more than triple in 2100, reaching 30 per cent that year.
7. Globally, the number of persons aged 60 or over is expected to more than triple by 2100, increasing from 784 million in 2011 to 2 billion in 2050 and 2.8 billion in 2100. Furthermore, already 65 per cent of the world's older persons live in the less developed regions and by 2050, 79 per cent will do so. By 2100, this figure will reach 85 per cent.
8. In ageing populations, the numbers of persons with older ages grow faster the higher the age range considered. Thus, whereas the number of persons aged 60 or over is expected to almost triple, that of persons aged 80 or over (the oldest-old) is projected to increase almost eight-fold, to reach 402 million in 2050 and 792 million in 2100. Today, just about half of the oldest-old live in developing countries but that share is expected to reach 69 per cent in 2050.
9. Although the population of all countries is expected to age over the foreseeable future, the population will remain relatively young in countries where fertility is still high, many of which are experiencing very rapid population growth. High population growth rates prevail in many developing countries, most of which are least developed. Between 2011 and 2100, the populations of 32 countries, the majority of which are least developed, will triple or more. Among them, the populations of Burkina Faso, Malawi, Mali, Niger, Somalia, Uganda, United Republic of Tanzania and Zambia are projected to increase by 500 per cent or more by 2100.

10. In sharp contrast, the populations of 49 countries or areas are expected to decrease between 2011 and 2050, 44 of which are expected to continue to decrease between 2050 and 2100. These countries include Belarus, Bosnia-Herzegovina, Bulgaria, Croatia, Cuba, Georgia, Japan, Latvia, Lithuania, Portugal, Republic of Moldova, Romania, the Russian Federation, Serbia, Ukraine and United States Virgin Islands, all of which are expected to see their populations decline by at least 10 per cent by 2050. Including those 44 countries, the populations in a total of 123 countries or areas are expected to decrease between 2050 and 2100, 22 of which are expected to see their populations decline by at least 20 per cent in that period.
11. Population growth remains concentrated in the populous countries. During 2011-2100, six countries are expected to account for half of the world's projected population increase: India, Nigeria, the United States of America, the Democratic Republic of Congo, the United Republic of Tanzania and Uganda, listed according to the size of their contribution to global population growth.
12. Fertility has continued to fall in the vast majority of countries in the less developed regions. The number of developing countries with high fertility (5 children or more per woman) declined from 59 in 1990-1995 to 27 in 2005-2010, and their share of the world population dropped from 13 per cent to 8 per cent. Over the same period, the number of developing countries with fertility levels that do not ensure the replacement of the population increased from 13 to 32.
13. Most developed countries have had below-replacement fertility (below 2.1 children per woman) for two or three decades. Among the 45 developed countries with at least 100,000 inhabitants in 2011, 42 had below-replacement fertility in 1990-1995 and all of them in 2005-2010. However, between the 2000-2005 and 2005-2010, 35 developed countries experienced slight increases in fertility. For the more developed regions as a whole, total fertility increased from 1.57 to 1.66 children per woman between those two periods. Yet, in 2005-2010, 25 developed countries, including Japan and most of the countries in Southern and Eastern Europe, still had fertility levels below 1.5 children per woman.
14. In 2005-2010, the 76 countries with below-replacement fertility accounted for 47 per cent of the world population. The most populous developing countries with below replacement fertility are China, Brazil, Viet Nam, the Islamic Republic of Iran, Thailand and the Republic of Korea, in order of population size.
15. Globally, total fertility is expected to fall from 2.52 children per woman in 2005-2010 to 2.17 in 2045-2050 and to 2.03 in 2095-2100 according to the medium variant. However, in the more developed regions, total fertility is projected to increase from 1.66 children per woman currently to 1.97 in 2045-2050 and 2.07 in 2095-2100. A major reduction of fertility is projected for the group of least developed countries (from 4.41 to 2.76 children per woman in 2045-2050 and to 2.13 in 2095-2100) and the fertility of the rest of the developing world is expected to drop from 2.41 children per woman currently to 2.00 in 2045-2050 and 1.97 in 2095-2100, thus nearly converging to the fertility levels by then typical of the developed world.
16. The median age, that is, the age that divides the population in two halves of equal size, is an indicator of population ageing. Globally, the median age is projected to increase from 29 to 38 years between 2011 and 2050 and from 38 to 42 years between 2050 and 2100. Europe has today the oldest population, with a median age of nearly 40 years, which is expected to reach 46 years in 2050 and then slightly decline to 45 years.

17. The median age is higher in countries that have been experiencing low fertility for a long time. In 2010, 18 developed countries or areas had a median age of 40 years or higher, up from 11 in 2005. Among developing countries or areas, only Hong Kong SAR China reached median ages above. The pervasiveness of population ageing will increase by 2050 when all 45 developed countries are projected to have median ages higher than 40 years and 55 developing countries will also have similarly high median ages. Between 2050 and 2100 another 57 developing countries will have such high median ages. Whereas today about 6 per cent of the world population lives in countries where median ages are 40 years or higher, the equivalent proportions in 2050 and 2100 are projected to be 41 per cent and 68 per cent, respectively.
18. Countries where fertility remains high and has declined only moderately will experience the slowest population ageing. By 2050, slightly more than one in five countries is projected to have a median age under 30 years (49 countries). The youngest populations will be found among the least developed countries, eighteen of which are projected to have median ages below 25 years in 2050. However, the pace of population aging in these countries after 2050 will speed-up. By 2100 only three countries (Malawi, Somalia and Zambia) are expected to have median age under 30 years with Zambia the youngest having a median age of 26.4 years.
19. Increasing longevity also contributes to population ageing. Globally, life expectancy at birth is projected to rise from 68 years in 2005-2010 to 76 years in 2045-2050 and to 81 years in 2095-2100. In the more developed regions, the projected increase is from 77 years in 2005-2010 to 83 years in 2045-2050 and to 88 years in 2095-2100, while in the less developed regions the increase is expected to be from 66 years currently to 74 years by mid-century and 80 years by the end of the century.
20. Life expectancy remains low in the least developed countries, at just 57 years in 2005-2010, and although it is projected to reach 69 years in 2045-2050 and 77 years in 2095-2100, realizing such increase is contingent on reducing the spread of HIV and combating successfully other infectious diseases. Similar challenges must be confronted if the projected increase of life expectancy in the rest of the developing countries, from under 68 years today to 76 years by mid-century and to 81 year by the end of the century, is to be achieved.
21. A major concern is that most developing countries are unlikely to meet the goal of reducing under-five mortality by two-thirds between 1990 and 2015, as called for in the Millennium Development Goals. According to the *2010 Revision*, 138 of the 153 developing countries with more than 100,000 inhabitants in 2011 will not reach that goal. Furthermore, 62 developing countries, located mainly in sub-Saharan Africa or belonging to the group of least developed countries, are projected to have in 2015 an under-five mortality higher than 45 deaths per 1000, the less demanding target set by the Programme of Action of the International Conference on Population and Development.
22. Among the more developed regions, Eastern Europe has the lowest life expectancy and it has experienced reductions in life expectancy at birth since the late 1980s. In 2005-2010 life expectancy in the region increased somewhat but at 69.7 years was lower than it had been in 1970-1975 (71.5 years). Despite having recorded some recovery since the late 1990s, Republic of Moldova, the Russian Federation and Ukraine have currently the lowest life expectancies among developed countries (below 70 years).

23. Although the HIV/AIDS epidemic continues to be a major issue of concern in the global health agenda, adult HIV prevalence reached a peak over the past decade or so in at least 85% of the 48 countries considered to be most affected by the epidemic and a growing number of them are reaching and maintaining lower prevalence levels. Nevertheless, in countries where prevalence has been high, the impact of the epidemic in terms of morbidity, mortality and slower population growth continues to be evident. Thus, in Southern Africa, the region with the highest prevalence of the disease, life expectancy has fallen from 61 years in 1990-1995 to 51 years in 2005-2010 and is only recently beginning to increase. Nevertheless, life expectancy in the region is not expected to recover the level it had in the early 1990s before 2035. As a consequence, the growth rate of the population in the region has plummeted, passing from 2.4 per cent annually in 1990-1995 to 1.0 per cent annually in 2005-2010 and is expected to continue declining for the foreseeable future.
24. Given the low fertility prevailing in developed countries, deaths are expected to exceed births over the foreseeable future. Consequently, the population of the more developed regions would be decreasing if the excess of deaths over births were not counterbalanced by a net migration gain. During 2010-2050, the net number of international migrants to more developed regions is projected to be 87 million, whereas the excess of deaths over births is 11 million, implying an overall growth of 76 million. During 2050-2100, the net number of international migrants to more developed regions is projected to be 49 million, whereas the excess of deaths over births is 24 million, indicating an overall growth of 25 million.
25. In 2005-2010, net migration in three countries or areas more than doubled the contribution of natural increase (births minus deaths) to population growth: Italy, Portugal and Japan. In addition, in a further 29 countries or areas, net migration counterbalanced totally the excess of deaths over births.
26. In terms of annual averages, the major net receivers of international migrants during 2010-2050 are projected to be the United States (924,000 annually), Canada (183,000), Spain (163,000), Italy (144,000) and the United Kingdom (143,000). The major countries of net emigration are projected to be China (-357,000 annually), India (-241,000), Mexico (-210,000), Pakistan (-194,000), Indonesia (-153,000) the Philippines (-152,000) and Bangladesh (-119,000). During 2050-2100, the major net receivers of international migrants are projected to be the United States (378,000 annually), Italy (79,000) and Canada (76,000); whereas the major net senders are projected to be China (208,000 annually), India (101,000), Pakistan (83,000), the Philippines (64,000) and Bangladesh (63,000). Although the current economic crisis may reduce migration flows in comparison to those registered over the recent past, the major economic and demographic asymmetries that will persist are likely to remain powerful generators of international migration over the medium-term future.

I. WORLD POPULATION TRENDS

A. POPULATION SIZE AND GROWTH

On 1 July 2011, the world population reached more than 6.9 billion with 5.7 billion (or 82 per cent of the world's total) living in the less developed regions (table I.1). Out of these, 851 million reside in the 48 least developed countries and account for 12.2 per cent of the world population. More developed countries, whose total population amounts to 1.2 billion inhabitants, account for 17.8 per cent of the world population (table I.2).

According to the medium variant, the world population is projected to reach 9.3 billion persons by 2050, that is, 2.3 billion more than in 2011, an increase close to the combined populations of China and India today. Most of this growth will be absorbed by developing countries. Between 2011 and 2050, the population of the more developed regions will remain largely unchanged at 1.3 billion inhabitants, but the population of the less developed regions is projected to rise from 5.7 billion in 2011 to 8 billion in 2050. At the same time, the population of the least developed countries is projected more than to double, from 851 million inhabitants in 2011 to more than 1.7 billion in 2050. Consequently, by 2050, 85.9 per cent of the world population is expected to live in the less developed regions, including 18.6 per cent in the least developed countries, whereas only 14.1 per cent will live in the more developed regions.

According to the medium variant, the world population is projected to reach 10.1 billion persons by 2100, that is, 3.1 billion more than in 2011, but only 819 million more than in 2050. During the second part of the 21st century, the growth of the world population will have occurred mainly in the less developed regions. The population of the more developed regions will remain stable at 1.3 billion, but the population of the less developed regions is projected to rise from 8 billion in 2050 to 8.8 billion in 2100. The population growth in the less developed regions will indeed happen among the least developed countries whose population is projected to increase by almost 964 million between 2050 and 2100. By 2100, almost 87 per cent of the world population is expected to live in the less developed regions, including 27 per cent in the least developed countries. By 2100, the least developed countries as a group would account for 31 per cent of the population living in the less developed regions, up from 15 per cent in 2011 and 22 per cent in 2050.

The world population in 2050 would be substantially higher if the decline in fertility projected in the medium variant fails to be realized. If fertility were to remain constant at current levels in all countries, world population would increase significantly by 2050, reaching 10.9 billion. In the high variant, where fertility is assumed to remain mostly half a child higher than in the medium variant, the world population in 2050 would reach 10.6 billion persons. In the low variant, where fertility is projected to be half a child lower than in the medium variant, world population would still grow, but only to reach 8.1 billion by 2050. According to the low variant, the population of the least developed countries would nearly double, to reach 1.5 billion by 2050, but the population of the more developed regions would decline to 1.16 billion.

Most of the world population lives in a few countries. In 2011, 37 per cent of the world population lived in China and India. A further eight countries accounted for a further 22 per cent of the earth's inhabitants, namely, the United States of America, Indonesia, Brazil, Pakistan, Nigeria, Bangladesh, the Russian Federation and Japan, in order of population size (tables S.1 and S.3). However, most of the countries of the world have small populations. Thus, 73 per cent of the 229 countries or areas covered by the *2010 Revision* had populations with fewer than 20 million inhabitants in 2011 and, as a group, they account for 10 per cent of the world's population.

By 2021, the population of India is projected to surpass that of China and the two will account then for about 36.1 per cent of the world population. By 2050, five least developed countries—Bangladesh, the Democratic Republic of the Congo, Ethiopia, the United Republic of Tanzania and Uganda—will be among the twenty most populous countries in the world. By 2100, among the twenty most populous countries in the world, nine will be least developed countries—the United Republic of Tanzania, the Democratic Republic of the Congo, Uganda, Bangladesh, Ethiopia, Zambia, Niger, Malawi and Sudan (tables S.2 and S.3).

Increments in the world population are also largely concentrated in a few countries, generally the most populous. Thus, during 2011-2050, eight countries—India, Nigeria, Pakistan, the United Republic of Tanzania, the United States, Democratic Republic of the Congo, Ethiopia and Philippines, in order of population increment—are expected to account for half of the projected population increase at the world level (table S.5).

Over most of human history, the world population grew very slowly if at all. Growth rates began increasing slowly during the 17th or 18th centuries as mortality started to decline. With accelerating gains in longevity, the growth rate of the world population increased, especially during the 20th century, when it reached a peak at 2 per cent per year in 1965-1970 (figure 2). Since then, the speed of population growth has been decelerating, largely as a result of falling fertility in the developing world. By 2005-2010, the population growth rate at the world level had reached 1.16 per cent per year and is projected to decline to 0.44 per cent per year by 2045-2050 and 0.06 by 2095-2100 (table S.7).

However, because fertility decline has not occurred simultaneously in all countries, the pace of population growth still differs considerably among development groups. Thus, whereas today the population of the more developed regions is rising at an annual rate of 0.41 per cent, that of the less developed regions is increasing almost four times as fast, at 1.33 per cent annually, and the least developed countries as a group are experiencing even more rapid population growth, at 2.21 per cent per year. Such differences are expected to persist until 2050 (table I.3). By that time, according to the medium variant, the population of the more developed regions will be nearly stagnating, whereas the population of the less developed regions will still be rising at an annual rate of 0.50 per cent per year. More importantly, the population of the least developed countries will likely be increasing at a robust annual rate of 1.42 per cent in 2045-2050, a rate that, if maintained, would lead to a doubling of the population every 49 years (figure 2). During the second half of the 21st century, the population of the less developed regions will reach a very low annual rate of population growth, similar to that of the more developed regions. Yet, the population growth rate of the least developed countries, albeit declining, will still amount to 0.53 per cent per year in 2095-2100, a rate that would produce a doubling of the population every 131 years.

B. POPULATION AGE COMPOSITION

The primary demographic consequence of fertility decline, especially if combined with increases in life expectancy, is population ageing, a process whereby the proportion of older persons in the population increases and that of younger persons declines. In 1950, just 8 per cent of the world population was aged 60 years or over. By 2011 that proportion had risen to 11.2 per cent and it is expected to reach 22 per cent in 2050 (table I.6). Globally, the number of older persons (aged 60 years or over) will increase by a factor of 2.6, passing from 784 million in 2011 to more than 2 billion in 2050. In contrast, the number of children (persons under age 15) is projected to decline over the next 40 years, passing from 1.85 billion in 2011 to 1.91 billion in 2050 and their share of the total population will drop from 26.6 per cent in 2011 to 20 per cent in 2050. During the second half of the 21st century, the number of older persons (aged 60 years or over) will increase by a further 600 million, to reach 2.8 billion in 2100, and the number of children will decrease by 200 million, to reach 1.8 billion in 2100.

Figure 1. Average annual rate of population change for the world and the major development groups, 1950-2100 (medium variant)

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2011). *World Population Prospects: The 2010 Revision*. New York: United Nations.

Increases in the median age, the age at which half the population is older and half is younger than that age, are indicative of population ageing (table I.4). In 2011, 22 countries, all of them developed countries except for Hong Kong Special Administrative Region of China, had a median age higher than 40 years. Japan led the group with a median age of 45.0 years, followed closely by Germany, with median age of 44.7 years, and Italy, with median age of 43.5 years (tables S.10 and S.11). In contrast, the median ages of Niger and Uganda in 2011 were below 16 years, making their populations the youngest on the planet.

By 2050, 100 countries are expected to have a median age above 40 years, 56 of which are located in the developing world. That is, population ageing, which is already pervasive in developed countries, is expected to be common in the developing world of the future and is projected to occur more rapidly in developing countries than it did in their developed counterparts. In 2100, it is anticipated that 158 countries will have a median age above 40 years, more than two thirds of which will be located in the developing world.

Despite the general trend toward population ageing, countries that still have relatively high fertility will have a younger population than the rest in 2050 (table I.6). Most least developed countries are in this group. In 2050, nine least developed countries are projected to have the youngest populations on Earth, with median ages below 24 years. They are: Zambia, Malawi, Niger, Somalia, the United Republic of Tanzania, Uganda, Mali, Burkina Faso, Nigeria and Chad, in increasing order according to the value of their respective median ages (table S.10). Because the least developed countries are expected to continue having some of the highest fertility levels on Earth after 2050, their populations will remain among the youngest in 2100. By that date, the median ages of the populations of Zambia, Somalia, Malawi, Niger,

TABLE I.3. AVERAGE ANNUAL RATES OF CHANGE OF THE POPULATION OF THE WORLD AND MAJOR AREAS, 1950-1980, 1980-2011, 2011-2050 AND 2050-2100 FOR DIFFERENT VARIANTS (PERCENTAGE)

Major area	1950-2011	1950-1980	1980-2011	2011-2050				2050-2100

NOTE: Refers only to countries or areas with 100,000 persons or more in 2011.

the United Republic of Tanzania, Burkina Faso, Guinea-Bissau, Nigeria and Mali will be the lowest on Earth, all being below 35 years.

The more developed regions have been leading the process of population ageing and their experience provides a point of comparison for the expected ageing of the population of the less developed regions. In 1950, the number of children (persons under age 15) in the more developed world was more than twice the number of older persons (those aged 60 years or over), with children accounting for 27.3 per cent of the total population and the elderly for only 11.7 per cent. By 2011, the proportion of older persons in the more developed regions had surpassed that of children (22.1 per cent versus 16.5 per cent) and in 2050, the proportion of older persons is expected to be about double that of children (31.9 per cent versus 16.3 per cent). In 2050, the number of older persons in more developed regions is projected to be more than four times their number in 1950 (418 million versus 95 million) while the number of children is projected to decline slightly from 222 million in 1950 to 218 million in 2050. Because the fertility of the more developed regions is projected to increase, albeit slowly, over most of the projection period, population ageing will slow down. As a result, between 2050 and 2100 the number of older persons in the more developed regions is expected to increase by only 15 million, to reach 433 million and the number of children under age 15 is also expected to increase, gaining 8 million, to reach 226 million (table I.6).

Until 2011, population ageing had been considerably slower in the less developed regions where fertility has been still relatively high. The proportion of children declined from 37.6 per cent in 1950 to 28.8 per cent in 2011, while the proportion of older persons increased from 6.3 per cent to 8.9 per cent. However, a period of more rapid population ageing lies ahead for the less developed regions. By 2050, their proportion of older persons is projected to reach 20.2 per cent, whereas their proportion of children is projected to decline to 21.1 per cent. After 2050, population ageing in the less developed regions will continue but at a slower pace. By 2100, the proportion of older persons is projected to increase to 27.3 per cent and the proportion of children is projected to decline to 18.1 per cent (table I.5).

Trends in the number of persons of working age (those aged 15 to 59 years) are particularly important for all countries. The proportion of the population in those ages is an important factor related to the potential for economic growth. In the more developed regions, the proportion of the population of working age decreased from 60.9 per cent in 1950 to 59.4 per cent in 1970 and then increased steadily to reach 63.0 per cent in 2005. Since then, that proportion has been declining. Its value is projected to drop from 61.4 per cent in 2011 to 51.5 in 2050 and then to fluctuate between a high of 51.9 in 2065 and a low of 50.6 in 2100 (table I.6). That is, the major change in the proportion of the population of working ages in the more developed regions will occur over the next 40 years if, as projected in the medium variant, the fertility of the more developed regions rises slowly toward replacement level for the rest of the century.

In the less developed regions, the proportion of the population of working age is expected to decline slightly, passing from 62.4 per cent in 2011 to 58.7 per cent in 2050 and 54.6 per cent in 2100. However, among the least developed countries, that proportion will rise from 54.9 per cent in 2011 to 60.3 per cent in 2050 and decline thereafter to 58.1 per cent in 2100, an increase that represents both an opportunity and a challenge: an opportunity to spur economic growth provided that the challenge of creating gainful employment for the growing numbers of persons of working age is met.

Among the older population, the number and proportion of the oldest-old, that is, persons aged 80 years or over, is rising. In 2011, there were 109 million oldest-old persons in the world, corresponding to 1.6 per cent of the world population (table I.6). By 2050, this segment of the population is projected to reach 402 million or 4.3 per cent of the world population and by 2100 it would ascend to 792 million or 7.8 per cent of the population. The group of oldest-old is the fastest growing segment of the world population. Particularly rapid increases in this group are expected in the less developed regions, where the

oldest-old are projected to increase from 56 million in 2011 to 280 million in 2050 and to 635 million in 2100, implying an average annual rate of increase of 4.2 per cent during 2011-2050 and of 1.6 per cent per year during 2050-2100 (table I.5). Over half of the oldest-old already live in the less developed regions but they are expected to become increasingly concentrated in developing countries. Thus, in 2050, 70 per cent of all persons aged 80 or over are expected to live in developing countries and by 2100 80 per cent are expected to do so.

In 2011, 71 countries had populations where persons aged 80 years or older accounted for more than 1.58 per cent of the population (the proportion of oldest-old in the world). The oldest-old accounted for over 6.6 per cent of the population of Japan and for more than 5.0 per cent of the populations of Italy, France, Sweden, Germany, Belgium, Spain and Greece, ordered according to the proportion of oldest-old (table S.9). By 2050, 97 countries are expected to have populations where persons aged 80 or over account for more than 4.32 per cent of the population (the proportion of the oldest-old at the global level in 2050). In Japan, Germany and 19 other countries the oldest-old are projected to account for over 10 per cent of the population. In 2100, the proportion of the oldest-old is projected to exceed 7.83 per cent (their share of the world population) in 130 countries and in 108 of them, the proportion of persons aged 80 years or over is projected to exceed 10 per cent.

Just as the overall population, the oldest-old tend to be concentrated in the most populous countries. In 2011, 19.4 million lived in China, 12 million in the United States and 8.7 million in India. In 2050, those countries will still have the largest numbers of persons aged 80 years or over: 98.3 million in China, 44.2 million in India and 31.7 million in the United States. By 2100, India is projected to have 130 million persons of aged 80 or over, China 107 million and the United States 52 million.

II. FERTILITY

According to the *2010 Revision*, total fertility—that is, the average number of children a woman would bear if fertility rates remained unchanged during her lifetime—is 2.52 children per woman in 2005-2010 at the world level (table II.1). This average masks the heterogeneity of fertility levels among countries and regions (figure 2). In 2005-2010, 75 countries or areas (44 of them located in the more developed regions) have fertility levels below 2.1 children per woman, that is, below replacement level¹, whereas 121 countries or areas (all of which are located in the less developed regions) have total fertility levels at or above 2.1 children per woman. Among these 121 countries, 26 have total fertility levels at or above 5 children per woman, 25 of which are least developed countries (table II.2).

TABLE II.1. ESTIMATED AND PROJECTED TOTAL FERTILITY FOR THE WORLD, MAJOR DEVELOPMENT GROUPS AND MAJOR AREAS, 1970-1975, 1990-1995, 2005-2010, 2045-2050 AND 2095-2100 ACCORDING TO DIFFERENT VARIANTS*

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2011). *World Population Prospects: The 2010 Revision*. New York: United Nations.

*NOTE: Refers only to countries or areas with 100,000 persons or more in 2010.

The 75 countries where total fertility is below replacement level in 2005-2010 account for 47.5 per cent of the world population or approximately 3.2 billion people. Countries with fertility at or above replacement level account for 3.5 billion people or 52.5 per cent of the world population.

Within the next decades, the number of countries with below-replacement fertility is expected to almost double to reach 132 in 2045-2050. This means that by mid-century 7 billion people or 76.7 per cent of the world population will be living in these countries. Under this medium fertility variant, it is assumed that 182 countries will reach below-replacement fertility by 2095-2100, and nearly 83 per cent of the world population will be living in a country where the average number of children per woman will be below 2.1.

These results differ substantially from previous revisions of the *World Population Prospects* because the new 2010 assumptions and the new projection model used take into greater account the unique fertility decline experience of each country and better use the experience of all other countries to inform future potential fertility trajectories. This means that, based on the very fast decline experienced in many countries, the future fertility decline in these countries is projected to happen faster and continue

¹ Replacement-level fertility is the level that needs to be sustained over the long run to ensure that a population replaces itself. For most countries having low or moderate mortality levels, replacement level is close to 2.1 children per woman.

further below replacement level than assumed in previous revisions because of the uncertainty about the level fertility will continue to decline before it starts to recover toward replacement level. While the fertility transition from high to low fertility is assumed to apply universally, its timing and especially the pace at which it occurs varies between countries, and for a small number of countries currently with high fertility (i.e., 5 children or more on average per woman) the projected declines are likely to occur at much slower pace than the average experience of all other countries as it was assumed in previous revisions. Ultimately by mid-century, only about a dozen of countries out of 68 currently are expected to still have above or equal to 3 children per woman on average. By 2045-2050, only 10 per cent of the world population is expected to live in such country compared to 18 per cent currently (table *S.12*).

Since, 1974, when the first World Population Conference was held in Bucharest, Romania, fertility has declined by more than 20 per cent in 135 developing countries and by over 50 per cent in 66 of them. The fastest fertility reductions, among countries with fertility levels greater or equal to 4 children per woman in 1975-1980, occurred in countries in Asia, including Maldives, the Islamic Republic of Iran, Oman, Viet Nam, United Arab Emirates, Bangladesh, Mongolia, Bhutan, Qatar. Fertility also declined rapidly in Algeria, Tunisia, Libyan Arab Jamahiriya in Northern Africa, Cape Verde in Sub-Saharan Africa, in Saint Lucia in Latin America, and Albania in Europe (table *S.13*). The average number of children in countries which have experienced over 50 per cent decline since 1970-1975 is currently below 2.31 children per woman on average instead of 5.76 children per woman thirty-five years ago.

Although most developing countries are already far advanced in the transition from high to low fertility, ten countries still have fertility levels of 6 children per woman or higher in 2005-2010 and in Niger total fertility is greater than 7 children per woman (table II.2 and table *S.12*), and the fertility in these country has decreased at most by about one child within the last 30 years (table *S.13*). Based on the experience of other countries with similar levels of fertility in the past, the fertility of those ten countries is projected to decline after 2010, at a pace of about one child per decade after 2020, and none is expected to reach 2.1 children per woman by 2045-2050 in the medium variant. As a result, their average fertility is expected to be around 3.5 children per woman and their population is expected nearly to triple, passing from 197 million in 2008 to 542 million in 2048, and could reach over 1.09 billion in 2098.

These ten countries are least developed countries—Afghanistan, Chad, the Democratic Republic of the Congo, Malawi, Mali, Niger, Somalia, Timor-Leste, Uganda, Zambia —and several are highly affected by the HIV/AIDS epidemic. Moreover, a number of them have been experiencing civil strife and political instability in recent years, factors that militate against the provision of basic services for the population. The continuation of rapid population growth poses serious challenges to their future development.

Despite the important contribution to population growth of high-fertility countries (those with a total fertility above 6 children per woman), these ten countries account today for less than 3 per cent of the world population and are expected to constitute respectively 6 and 11 per cent of the world population by 2048 and 2098, according to the medium variant. Countries with total fertility ranging from 4 to 6 children per woman account today for 10 per cent of the world population, but will account for less than 2 per cent by 2048 (table II.2) because their fertility is expected to continue to decline from about 5 children per woman on average currently to 2.7 children per woman on average by 2045-2050, and to reach 2.1 children per woman by 2075-2080.

In 2008, the majority of people in the developing world live in the 58 countries with total fertility ranging from 2.1 to 4 children per woman, which account for 45 per cent of the world population. Most of those countries are projected to have a total fertility below replacement level by 2040-2045 or even earlier, according to the medium variant. Overall, 136 countries or areas are projected to have below-replacement

*NOTE: Refers only to countries or areas with 100,000 persons or more in 2010.

fertility in 2045-2050, with 85 having a total fertility equal to or lower than 1.85 children per woman. As a result, according to the medium variant, 77 per cent of the world population is expected to live in countries with below-replacement fertility in 2045-2050. This percentage is expected to increase up to 83 per cent by the end of the century, but by then 171 countries are assumed to have reached a sub-replacement fertility level between 1.85 and 2.1 children per woman on average.

Fertility levels in developed countries, many of which experienced a “baby-boom” during the 1950s and 1960s, have generally declined since the early 1970s to below-replacement level. In fact, in 1970-1975, 18 countries out of the 45 developed countries in the world already had below-replacement fertility. By 2005-2010, almost all developed countries had reached fertility levels below 2.1 children per woman (only New Zealand, Iceland and Ireland have fertility levels equal or just above 2.1). Among them, 14 had reached historically unprecedented low fertility levels (below 1.4 children per woman), with Bosnia and Herzegovina, Slovakia, Poland, Japan, Malta and Romania exhibiting the lowest levels in the developed world. But the lowest fertility levels (below 1.3 children per woman) are currently observed in China, Hong Kong SAR and Macao SAR as well as Singapore and the Republic of Korea (table S.12).

At the world level, the medium variant projects total fertility to be 2.17 children per woman in 2045-2050 (table II.1), with a convergence between countries which leads to 1.97 children per woman in the more developed regions and 2.19 children per woman in the less developed regions. That is, although the difference in total fertility between the more and the less developed regions narrows considerably by mid-century, the less developed regions are still expected to have a higher total fertility than the more developed regions, and some regions like Africa to have on average a fertility about one child higher than in Asia or Latin America. That difference persists in all projection variants. Total fertility in the low variant is expected to be 1.47 children per woman in the more developed regions and 1.73 children per woman in the less developed regions. In the high variant, total fertility is projected to be 2.46 children per woman in the more developed regions and 2.66 children per woman in the less developed regions.

III. MORTALITY AND THE DEMOGRAPHIC IMPACT OF HIV/AIDS

A. TRENDS AND PROSPECTS IN WORLD MORTALITY

The twentieth century witnessed the most rapid decline in mortality in human history. In 1950-1955, life expectancy at the world level was 48 years and it had reached 68 years by 2005-2010. Over the next 45 years, life expectancy at birth at the global level is expected to reach 76 years in 2045-2050 and 81 years in 2095-2100 (table III.1). The more developed regions already had a high expectation of life in 1950-1955 (66 years) and have since experienced further gains in longevity. By 2005-2010 their life expectancy stood at 76.9 years, 11 years higher than in the less developed regions where the expectation of life at birth was 65.9 years. Although the gap between the two groups is expected to narrow between 2005 and mid-century, in 2045-2050 the more developed regions are still expected to have considerably higher life expectancy at birth than the less developed regions (82.7 years versus 74.4 years). Throughout 2010-2100, systematic progress against mortality is further expected to increase life expectancy at birth up to 88.2 years in the more developed regions and 80.1 years in the less developed regions thereby further reducing the gap in mortality between the two groups.

TABLE III.1. LIFE EXPECTANCY AT BIRTH FOR THE WORLD, MAJOR DEVELOPMENT GROUPS AND MAJOR AREAS, 2005-2010 AND 2045-2050

Source: Population Division of the Department of Economic and Social Affairs of the United Nations Secretariat (2011). *World Population Prospects: The 2010 Revision*. New York: United Nations.

The 48 least developed countries, which include 26 of the countries that are highly affected by HIV/AIDS, have been experiencing higher mortality than other development groups. Their life expectancy at birth was 56.9 years in 2005-2010 and is expected to remain relatively low, reaching 69.1 years in 2045-2050. During 2050-2100, provided a continued decline in mortality rates from HIV/AIDS as well as from other major causes of death, it is conceivable that life expectancy at birth will further climb to reach 77.5 years in 2095-2100. This gain is the most important factor in reducing gap in life expectancy between the more developed and the less developed groups of countries.

The general upward trend in life expectancy for the more developed and the less developed regions (figure 4) conceals different trends among the world's major areas (figure 5). In Asia, Latin America and the Caribbean, Northern America and Oceania, life expectancy has been increasing at a steady pace. In contrast, Europe as a whole experienced a slowdown in the increase of life expectancy starting in the late

1960s and stagnating levels since the late 1980s. This trend is the result of severe reductions in life expectancy in countries of Eastern Europe, particularly in the Russian Federation and the Ukraine. The remaining regions of Europe have had increasing life expectancies which are currently equal to or higher than that of Northern America.

Africa has the lowest life expectancy levels of any major area. Furthermore, life expectancy in Africa has virtually stagnated since the late 1980s. While this trend is due in large part to the HIV/AIDS epidemic, other factors have also played a role, including armed conflict, economic stagnation, and resurgent infectious diseases such as tuberculosis and malaria. The recent negative developments in many countries of Africa represent major set backs in reducing mortality. Only in 2005-2010 is life expectancy expected to begin rising again and, provided efforts to reduce the expansion of the HIV/AIDS epidemic and to treat those affected by it succeed, it is expected to continue rising to reach 68 years in 2045-2050 and 77.1 in 2095-2100.

However, even if these gains materialize, by mid-century the population of Africa is still expected to be subject to the highest mortality levels in the world, with its overall life expectancy being 8 years lower than the next lowest one, that of Asia.

In nearly all countries of the world, female life expectancy at birth is higher than that of males. At the world level, females have a life expectancy of 70 years in 2005-2010, compared to 66 years for males (table III.2). The female advantage is considerably larger in the more developed regions (7 years) than in the less developed regions (3.5 years). The gap between male and female life expectancy is particularly narrow in the least developed countries (2 years). At the world level, a difference of 4.8 years between female and male life expectancy is expected to persist until 2045-2050, but whereas the female to male gap in life expectancy is expected to narrow in the more developed regions, it is expected to widen in the less developed regions. By 2095-2100, the gap between male and female life expectancy is expected to narrow on the world level and in all regions except the least developed countries where it is expected to stabilize since 2045-2050 at about 4 years.

Under-five mortality, expressed as the probability of dying between birth and the exact age of five, is an important indicator of development and the well-being of children. In 1950-1955, 20 per cent (203 deaths per 1,000 births) of all children born worldwide did not reach their fifth birthday. By 2005-2010, this rate had fallen to 66 deaths per 1,000 births (table S.18). Although child mortality has fallen in all major areas, sub-Saharan Africa has lagged behind in achieving lower levels of child mortality (figure 6). In the 1950s, sub-Saharan Africa and South-Central Asia had similarly high levels of child mortality and both experienced significant reductions until the 1980s but thereafter, the pace of decline in child mortality in sub-Saharan Africa slowed down. As a result, by 2005-2010, under-five mortality had reached 76 deaths per 1,000 births in South-Central Asia, but it was still a high 136 deaths per 1,000 births in sub-Saharan Africa.

B. THE DEMOGRAPHIC IMPACT OF AIDS

More than thirty years into the HIV/AIDS epidemic, its effects on the populations of the highly-affected countries is evident. In the *2010 Revision*, the impact of HIV/AIDS is explicitly modelled for 48 countries, down from 58 in the *2008 Revision*. In most of these countries, HIV prevalence reached 1 per cent or higher in the period from 1980 to 2010 among the population aged 15-49 years. Four populous countries with lower prevalence levels were also included because they have a large number of persons living with HIV. They are China, India, Russian Federation, and the United States of America.

Among the 48 highly affected countries, 37 are in Africa, three in Asia, six in Latin America and the Caribbean, one in Europe and one in Northern America. Together they account for 28.9 million of the 33.3 million HIV-infected adults and children estimated to be alive in 2009 or 87 per cent of the world total.

The dynamics of the HIV/AIDS epidemic as reflected in the *2010 Revision* are consistent with the estimates of HIV prevalence in 2009 as reported by UNAIDS¹ for each country. Beginning in 2009, the *2010 Revision* assumes that changes in behaviour, along with treatment, will reduce the chances of infection. Rates of recruitment into high-risk groups are assumed to decline as well. In light of major expansions in antiretroviral therapy (ART) coverage, average survival of those infected is expected to increase at a rate determined by projected levels of ART coverage and efficacy. However, because the epidemic is still expanding, some countries are expected to experience increasing levels of HIV prevalence over the medium-term future. Nevertheless, in nearly all highly affected countries, HIV prevalence is projected to be lower in 2025 than in 2009 (table *S.19*).

In the *2010 Revision*, the estimated and projected long-term impact of HIV/AIDS is somewhat less severe than that projected in the *2008 Revision*. Part of this reduction is due to the incorporation of revised and lower estimates of HIV prevalence for several countries where nationally representative data on the epidemic have become available. Another part stems from the assumption that antiretroviral therapy will reach an ever increasing proportion of the persons who need it and that, as a result, those persons will not only survive longer but will be less infectious. However, realization of these projections is contingent on sustained commitment by Governments to assure treatment for those infected and to promote preventive measures and behavioural changes among the uninfected.

The *2010 Revision* confirms yet again the devastating toll AIDS has in terms of increased morbidity, mortality and population loss. Life expectancy in the most affected countries already shows dramatic declines. In Botswana, where HIV prevalence is estimated at 24.8 per cent in 2009 among the population aged 15-49 years, life expectancy has fallen from 64 years in 1985-1990 to 49 years in 2000-2005. By 2005-2010, life expectancy is expected to increase again to 53 years as a result of declining HIV prevalence and increased access to anti-retroviral therapy. In Southern Africa as a whole, where most of the worst affected countries are, life expectancy has fallen from 61 to 51 years over the last 20 years. While the impact in Southern Africa is particularly stark, the majority of highly affected countries in Africa have experienced declines in life expectancy in recent years because of the epidemic.

In countries where HIV prevalence rates are lower, AIDS has mainly slowed down the increase in life expectancy. To assess the impact of the disease on life expectancy in these countries, the medium variant projections are compared with a hypothetical scenario in which AIDS does not exist. One can thus conclude that in 2005-2010, for instance, life expectancy is expected to be lower than it would have been in the absence of AIDS by 0.69 years in Eritrea, by 1.03 years in the Russian Federation, and 1.14 years in Sierra Leone. A larger impact is yet to come in many countries, such as Gambia, where the impact of AIDS on life expectancy relative to the No-AIDS scenario is projected to increase from 0.79 years in 2005-2010 to 1.21 years in 2010-2015. Similarly, in Equatorial Guinea, that difference is projected to rise from 1.74 year in 2005-2010 to 2.33 years by 2010-2015.

The toll that HIV/AIDS is taking is already retarding progress in reducing child mortality. Thirty-five per cent of children infected through mother-to-child transmission are estimated to die before their first birthday, and 61 per cent die by age five if no treatment provided. The impact of HIV on child mortality is particularly dramatic in countries that had achieved relatively low levels of child mortality

¹ UNAIDS. (2010). *Global report: UNAIDS report on the global AIDS epidemic 2010*. UNAIDS/10.11E | JC1958E. Geneva, 2010. 362 p. - http://www.unaids.org/globalreport/Global_report.htm.

before the epidemic began. In Zimbabwe, for instance, where under-five mortality was one of the lowest in sub-Saharan Africa, it has risen from 84 child deaths per 1,000 births in 1985-1990 to 111 per 1,000 in 2000-2005 and is projected to decline to 71 per 1,000 in 2010-2015. In Swaziland, under-five mortality has risen from 108 to 128 deaths per 1,000 births between 1985-1990 and 2000-2005, and is expected to decline to 92 deaths per 1,000 in 2010-2015. The impact of HIV/AIDS on child mortality is projected to decrease in the future with improved prevention of mother-to-child transmission and expanding coverage for HIV/AIDS treatment.

AIDS reshapes the percentage distribution of deaths by age. In 1985-1990, deaths in Southern Africa were concentrated among young children and older adults (figure 7), and adults aged 20 to 49 years accounted for only 21 per cent of all deaths. By 2005-2010, a shift had taken place in the distribution of deaths by age, with 50 per cent of all deaths occurring between the ages of 20 and 49. Such large increases in mortality deplete the cohorts that are in the prime of their working and parental careers, creating the potential for severe shocks to economic and societal structures.

AIDS-related mortality and its impact on the potential number of births are reshaping the age structure of populations in the affected countries. Figure 8 shows the effect on the population of Southern Africa in 2015 by comparing the age distribution resulting from the No-AIDS scenario with that projected under the medium variant. The population aged 15 or over is 12 per cent smaller according the medium variant than according to the No-AIDS scenario. The reduced size of cohorts under age 15 is partly due to the deaths of large numbers of women during the reproductive ages and to the lower survival prospects of infected children. Total population in Southern Africa in 2015 is projected to be 59.6 millions or 11 per cent lower than according to the No-AIDS scenario.

Despite the effect of the epidemic on reducing population growth rates, the populations of affected countries are generally expected to be larger by mid-century than today, mainly because most of them maintain high to moderate fertility levels. In fact, owing to the downward revision of the prevalence of HIV/AIDS combined with the expected expansion of access to anti-retroviral therapy and efforts to control the further spread of HIV, all the countries with the highest prevalence in 2009 are expected to experience positive population growth rates between 2005 and 2050.

IV. INTERNATIONAL MIGRATION

Estimates of net migration between the major development groups show that since 1960 the more developed regions have been net gainers of emigrants from the less developed regions (table IV.1). Furthermore, net migration to the more developed regions has been increasing steadily from 1960 to 2010. During 2000-2010, the more developed regions were gaining annually 3.4 million migrants. About 39% of that net flow was directed to Northern America (1.33 million annually). During 2000-2010, the level of net migration to the more developed regions as a whole changes moderately, reaching a peak of 3.4 million migrants annually. Over the rest of the projection period, net migration to the more developed regions is projected to decline smoothly to about 1.9 million per year during 2040-2050, of which 1.1 million are directed to Northern America.

With respect to the other major areas, Asia was by far the major source of migrants during 2000-2010 (1.6 million annually), followed by Latin America and the Caribbean (1.1 million annually) and then Africa (0.6 million annually). Over the projection period, about half of all the net number of emigrants from the less developed regions are expected to be from Asia, between 20 per cent to 30 per cent from Latin America and the Caribbean, and the remaining from Africa.

At the country level, during 2000-2010, 32 of the 45 developed countries have been net receivers of international migrants. This group includes traditional countries of immigration such as Australia, Canada, New Zealand and the United States, most of the populous countries in Northern, Southern and Western Europe as well as the Russian Federation and Japan. The movement of people from less developed regions to more developed regions has dominated the world migration patterns for almost half a century, but flows among developing countries have also been important. Several developing countries or areas have been attracting migrants in large numbers, including, Israel, Kuwait, Malaysia, Qatar, Saudi Arabia, Singapore, South Africa, Thailand and the United Arab Emirates. Jordan and the Syrian Arab Republic have been the primary receivers of refugees from Iraq. Many African countries have been the destination of refugee flows from neighbouring countries.

During 2000-2010, the countries having the highest levels of net emigration included Bangladesh, China, India, Indonesia, Mexico and the Philippines. Pakistan also registered high levels of net emigration, partly as a result of the repatriation of Afghani refugees.

International migration is the component of population change most difficult to measure and estimate reliably. Thus, the quality and quantity of the data used in the estimation and projection of net migration varies considerably by country. Furthermore, the movement of people across international boundaries, which is very often a response to changing socio-economic, political and environmental forces, is subject to a great deal of volatility. Refugee movements, for instance, may involve large numbers of people moving across boundaries in a short time. For these reasons, projections of future international migration levels are the least robust part of current population projections and reflect mainly a continuation of recent levels and trends in net migration.

TABLE IV.1. AVERAGE ANNUAL NET NUMBER OF MIGRANTS PER DECADE BY DEVELOPMENT GROUP AND MAJOR AREA, 1950-2050

V. ASSUMPTIONS UNDERLYING THE 2010 REVISION

The preparation of each new revision of the official population estimates and projections of the United Nations involves two distinct processes: (a) the incorporation of all new and relevant information regarding the past demographic dynamics of the population of each country or area of the world; and (b) the formulation of detailed assumptions about the future paths of fertility, mortality and international migration. The data sources used and the methods applied in revising past estimates of demographic indicators (i.e., those referring to 1950-2010) are presented online¹ and in an Excel file (WPP2010_F02_METAINFO.XLS).

The future population of each country is projected starting with an estimated population for 1 July 2010. Because population data are not necessarily available for that date, the 2010 estimate is derived from the most recent population data available for each country, obtained usually from a population census or a population register, projected to 2010 using all available data on fertility, mortality and international migration trends between the reference date of the population data available and 1 July 2010. In cases where data on the components of population change relative to the past 5 or 10 years are not available, estimated demographic trends are projections based on the most recent available data. Population data from all sources are evaluated for completeness, accuracy and consistency, and adjusted as necessary.

To project the population until 2100, the United Nations Population Division uses assumptions regarding future trends in fertility, mortality and international migration. Because future trends cannot be known with certainty, a number of projection variants are produced. The following paragraphs summarize the main assumptions underlying the derivation of demographic indicators for the period starting in 2010 and ending in 2100.

A. FERTILITY ASSUMPTIONS: CONVERGENCE TOWARD TOTAL FERTILITY AROUND REPLACEMENT LEVEL

The fertility assumptions are described in terms of the following groups of countries:

- *High-fertility countries*: Countries that until 2010 had no fertility reduction or only an incipient decline;
- *Medium-fertility countries*: Countries where fertility has been declining but whose estimated level was still above 2.1 children per woman in 2005-2010;
- *Low-fertility countries*: Countries with total fertility at or below 2.1 children per woman in 2005-2010.

1. Medium-fertility assumption

In the *2010 Revision of the World Population Prospects* a new, probabilistic method for projecting total fertility has been used. This new method was developed in collaboration with the Probabilistic Projections Group of the Center for Statistics and the Social Sciences (CSSS) of the University of

¹ Data sources and related meta-information for the *2010 Revision of the World Population Prospects* are available for each country from the following web page: <http://esa.un.org/unpd/wpp/Documentation/data-sources.htm>

Washington². The method is based on empirical fertility trends estimated for all countries of the world for the period 1950 to 2010³.

There has been a general consensus that the evolution of fertility includes three broad phases (see Figure 9): (i) a high-fertility pre-transition phase, (ii) the fertility transition itself and (iii) a low-fertility post-transition phase during which fertility will probably fluctuate around and remain close to replacement level (or converge towards it). These historic trends of fertility decline are re-estimated every second year by the United Nations Population Division, using the most recent empirical evidence from censuses, surveys, registers and other sources and after extensive re-evaluation of past historical trends in the light of all the information available and internal consistency checks with intercensal cohorts.

In past revisions of the *World Population Prospects* it was assumed that countries in the transition from high to low fertility will ultimately approach a fertility floor of 1.85 children per woman, regardless of their current position in the fertility transition. The transition from the current level of fertility to the fertility floor was expressed by three models of fertility change over time. These fertility projection models have been formalized since the *2004 Revision* using a double-logistic function, defined by six deterministic parameters⁴. For countries that were below replacement level, a much simpler model of fertility change was used. In general, it was assumed that fertility would recover from very low levels of fertility, following a uniform pace that would also converge to the fertility floor of 1.85 children per woman, just as in the high and medium fertility countries.

The new probabilistic method that was used in the *2010 Revision* for projecting total fertility consists of two separate processes:

The first process models the sequence of change from high to low fertility (phase II of the fertility transition). For countries that are going through this fertility transition, the pace of the fertility decline is decomposed into a systematic decline and random distortion terms. The pace of the systematic decline in total fertility is modelled as a function of its level, based on the current UN methodology using a double-logistic decline function. The parameters of the double-logistic function are estimated using a Bayesian Hierarchical Model (BHM), which results in country-specific *distributions* for the parameters of the decline. These distributions are informed by historical trends within the country, as well as the variability in historical fertility trends of all countries that have already experienced a fertility decline. This approach not only allows to better take into account the historical experience of each country, but also to reflect the uncertainty about future fertility decline based the past experience of all other countries at similar level of fertility. Under these conditions, the pace of decline and the limit up to which fertility will decline vary for each projected trajectory. The model is hierarchical because in addition to the information available at the country level, a second-level (i.e., the world's experience through the information of all the countries) is used to inform the statistical distributions of the parameters of the double-logistic. Especially for countries at the beginning of their fertility transition, limited information exists as to their speed of decline and future trajectories, so the future potential trajectories (and speed of decline) are mostly informed by the world's experience and the variability in trends experienced in other countries at similar

² Alkema L., A.E. Raftery, P. Gerland, S.J. Clark, F. Pelletier, T. Buettner, G.K. Heilig (2011). Probabilistic Projections of the Total Fertility Rate for All Countries. *Demography*, vol. 48, number 3, pp. 815-839, doi: 10.1007/s13524-011-0040-5 and *Working Paper of the Center for Statistics and the Social Sciences*, University of Washington, 2010, vol. 97. URL <http://www.csss.washington.edu/Papers/wp97.pdf>

³ The initial version of this new approach was developed and tested using data from the 2008 revision, and the results were presented to a panel of experts during an Expert Group Meeting on Recent and Future Trends in Fertility: United Nations, Department of Economic and Social Affairs, Population Division (2009). *Expert Group Meeting on Recent and Future Trends in Fertility*. New York, 2-4 December 2009. <http://www.un.org/esa/population/meetings/EGM-Fertility2009/egm-fertility2009.html>

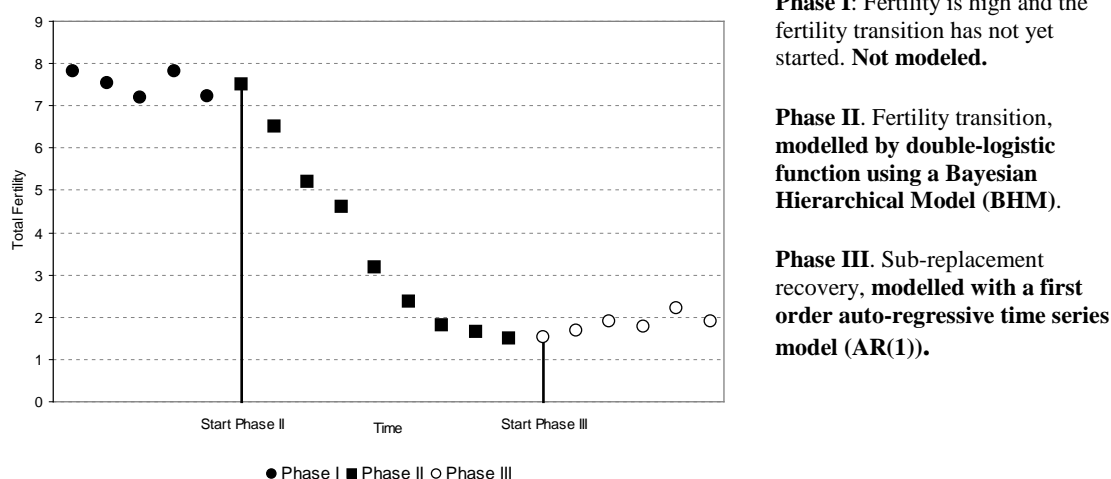

⁴ United Nations, Department of Economic and Social Affairs, Population Division (2006). *World Population Prospects. The 2004 Revision*, Vol. III, Chapter VI. Methodology of the United Nations population estimates and projections, pp. 100-104. http://www.un.org/esa/population/publications/WPP2004/WPP2004_Volume3.htm

fertility levels in the past. The Bayesian statistical approach itself is particularly adapted to estimate the parameters of the double-logistic model even when the number of empirical observations for each country is very limited (i.e., about 100 countries started their fertility transition since the 1960s and have nine or fewer observations).

The second component of the projection model deals with countries once they have completed the demographic transition, and reached Phase III and potentially sub-replacement fertility. A time series model is used for projecting fertility, assuming that in the long term the total fertility will approach and fluctuate around the replacement-level of 2.1 children per woman. The time series model uses the empirical information from countries that have had documented fertility increases from a sub-replacement level after a completed fertility transition. The assumption that fertility will converge toward and fluctuate around replacement-level the long run is driven by the extension of the projection horizon from 2050 to 2100 between the *2008 and 2010 Revisions*, and the underlying assumption of a population stabilization within 3-4 generations. The long term assumption of a fertility recovery is supported by the experience of many below-replacement fertility countries in Europe and East Asia⁵.

The two processes are schematically explained in Figure 9. During the observation period, the start of Phase II is determined by examining the maximum total fertility (or more precisely, the most recent local maximum within half a child of the global maximum to exclude random fluctuations in Phase I): the start of Phase II is deemed to be before 1950 for countries where this maximum is less than 5.5, and at the period of the local maximum for all other countries. The end of Phase II during the observation period is defined as the midpoint of the first two increases below 2 (if observed, else a country is still in Phase II).

To construct projections for all countries still in Phase II, the BHM model is used to generate 100,000 double-logistic curves for all countries that have experienced a fertility decline (see example in figure 10), representing the uncertainty in the double-logistic decline function of those countries (graphs of this double-logistic curve are available online⁶). The sample of double-logistic curves is then used to calculate 100,000 total fertility projections for all countries which have not reached Phase III in 2005-2010. For each trajectory, at any given time, the double-logistic function gives the expected decrement in total fertility based on its current level. A distortion term is added to the expected decrement to calculate the projected change in total fertility. (This distortion term represents the deviations of fertility decrements from the double-logistic curve, as observed in past declines.)

Once a trajectory has decreased to a level that is around or below replacement-level fertility, and after the pace of the fertility decline has decreased to zero, future changes of fertility are calculated using a time series model of fertility recovery that is informed by the countries that have experienced fertility increases.

Figure 10. Total fertility decrements and projection intervals of double-logistic curves for Algeria (systematic decline part)

NOTE: The observed five-year decrements by level of total fertility are shown by black dots. For clarity, only 80 trajectories from 100,000 are displayed. The median projection is the solid bold red line, and the 80% and 95% projection intervals are displayed as dashed and dotted red lines respectively.

An additional innovation in the *2010 revision* of the *World Population Prospects* is the removal of the 1.85 floor used in previous revisions as stabilization level after the fertility transition; the total fertility is now allowed to decrease *below* replacement level (i.e., 2.1 children per woman) in the projections because of the uncertainty up to which level fertility will decline (end of Phase II) before it starts to

⁶ United Nations, Department of Economic and Social Affairs, Population Division (2011): *World Population Prospects: The 2010 Revision*. New York. Online plots of total fertility decline curves (based on Double-Logistic function) from the Bayesian Hierarchical Model (BHM): median, 80% and 95% projection intervals: http://esa.un.org/unpd/wpp/fertility_figures/interactive-figures_DL-functions.htm

recover toward replacement level (start of Phase III). The pace of the fertility change, the level and timing when Phase II stops and Phase III starts vary for each of the 100,000 projected trajectories for a country that has not reached Phase III in 2005-2010: Its future trajectories are a combination of total fertility in Phase II and Phase III until Phase III has started in all trajectories. For countries that are already in Phase III, the time series model for that phase is used directly.

For each country, the end result is 100,000 projected country trajectories. The median of these 100,000 trajectories is used as the medium fertility variant projection in the *World Population Prospects*. To evaluate future trends in fertility, 80% and 95% projection intervals are also calculated (see figure 11 for Algeria, additional graphs are available online for all countries⁷). For countries which have not reached Phase III in 2005-2010, the projected median trajectory reflects the uncertainty as to when the fertility transition will end and at which level.

Figure 11. Probabilistic trajectories of projected total fertility (2010-2100) for Algeria

NOTE: For clarity, only 80 trajectories from 100,000 are displayed. The median projection is the solid bold red line, and the 80% and 95% projection intervals are displayed as dashed and dotted red lines respectively. The high-low fertility variants in the 2010 Revision correspond to +/- 0.5 child around the median trajectory displayed as blue dashed lines.

For a small set of countries which are still at the very early stage of their fertility transition (e.g., Burkina Faso, Congo, Equatorial Guinea, Guinea-Bissau, Mali, Mayotte, Niger, Nigeria, Rwanda, United Republic of Tanzania, Yemen) or have experienced recent fertility stalling (e.g., Israel, Kenya, Malawi, Somalia, Zambia), some post-adjustment was performed to preserve a smoother continuity with the recent trend in the past decade. In these countries, fertility decline has been much slower than typically experienced in the past decades by other countries at similar levels of fertility. As seen in Figure 12 for Kenya, fertility decline has been stalling at around 5 children per woman for the past decade: the observed

⁷ United Nations, Department of Economic and Social Affairs, Population Division (2011): *World Population Prospects: The 2010 Revision*. New York. Online plots of projections of total fertility: median, 80% and 95% projection intervals, high and low WPP fertility variants: http://esa.un.org/unpd/wpp/fertility_figures/interactive-figures_TF-trajectories.htm

decline between 2000-2010 was much smaller than in previous periods (≤ 0.2 child per woman by 5-year period), especially compared to other countries at similar level of fertility in the past. In such cases, the double-logistic model does not fit well the recent observations, and the projections are adjusted using the difference between the observed and expected decrement in the last period. Specifically, in the first and second projection periods, a decreasing proportion of this difference is added to the expected decrement, such that the adjusted expected decrement in those periods takes into account the difference between the double-logistic and observed decrement in the last observation period. Figure 13 shows the unadjusted and adjusted projection of total fertility for Kenya.

Figure 12. Total fertility decrements and projection intervals of double-logistic curves for Kenya

NOTE: The black dots represent the observed decrements, which are much smaller than the double-logistic-decrements in the last two observation periods because of a stall in the fertility decline. For clarity, only 80 trajectories from 100,000 are displayed.

Figure 13. Probabilistic trajectories of projected total fertility (2010-2100) for Kenya (adjusted)

NOTE: For clarity, only 80 trajectories from 100,000 are displayed.

In addition, for seven countries with fertility already around replacement levels (i.e., 2.1 children per woman) which have experienced recent up-surge of fertility since mid-2000 (e.g., Australia, Azerbaijan, Kazakhstan, Kyrgyzstan, Iceland, Mongolia, New Zealand), only the phase III model was applied to insure consistency with the historical and regional context, and demographic trends of these countries. Figure 14 shows for Kazakhstan the adjusted median projection compared to the unadjusted one which is a combination of trajectories based on Phases II and III (and assume greater uncertainty as to the completion of the fertility transition).

Figure 14. Probabilistic trajectories of projected total fertility (2010-2100) for Kazakhstan (adjusted)

NOTE: For clarity, only 80 trajectories from 100,000 are displayed.

The results of this new modelling approach are country-specific projections of total fertility that are fully reproducible and take into account past empirical trends. Extensive documentation for all countries and areas has been posted online⁸, and further details about the methodology are available from Alkema et al.⁹. In addition, an open-source and portable software implementation of the new UN approach to project total fertility, based on the R statistical language, developed by Sevcikova et al.¹⁰ is available as a fully documented R package (bayesTFR¹¹) through the public R CRAN archive together with a user-friendly Graphical User Interface (bayesDem¹²). Version 1.3-0 of the package was used to compute the final set of projections used for the *2010 Revision of the World Population Prospects*¹³.

¹³ The estimates of the double logistic parameters are based on three parallel chains of 62,000 iterations discarding the first 2,000 of each chain to yield a total of 180,000 samples of all model parameters. For each country, 100,000 trajectories were projected, and used to derive the median and other projection intervals. The AR(1) parameters used for the Phase III were estimated using maximum-likelihood estimation based on 55 empirical observations of countries having already experienced Phase III. Total computation time was about 7 days on a 32-bit Windows server. The seed of the random number generator for the Markov Chain Monte Carlo estimation used was: 20110206.

2. High-fertility assumption

Under the high variant, fertility is projected to remain 0.5 children above the fertility in the medium variant over most of the projection period. By 2020-2025, fertility in the high variant is therefore half a child higher than that of the medium variant. That is, countries reaching a total fertility of 2.1 children per woman in the medium variant have a total fertility of 2.6 children per woman in the high variant.

3. Low-fertility assumption

Under the low variant, fertility is projected to remain 0.5 children below the fertility in the medium variant over most of the projection period. By 2020-2025, fertility in the low variant is therefore half a child lower than that of the medium variant. That is, countries reaching a total fertility of 2.1 children per woman in the medium variant have a total fertility of 1.6 children per woman in the low variant.

4. Constant-fertility assumption

For each country, fertility remains constant at the level estimated for 2005-2010.

5. Instant-replacement assumption

For each country, fertility is set to the level necessary to ensure a net reproduction rate of 1 starting in 2010-2015. Fertility varies over the rest of the projection period in such a way that the net reproduction rate always remains equal to unity thus ensuring, over the long-run, the replacement of the population.

B. MORTALITY ASSUMPTIONS: INCREASING LIFE EXPECTANCY EXCEPT WHEN AFFECTED BY HIV/AIDS

1. Normal-mortality assumption

Mortality is projected on the basis of models of change of life expectancy produced by the United Nations Population Division. These models produce smaller gains the higher the life expectancy already reached. The selection of a model for each country is based on recent trends in life expectancy by sex. For countries highly affected by the HIV/AIDS epidemic, the model incorporating a slow pace of mortality decline has generally been used to project a certain slowdown in the reduction of general mortality risks not related to HIV/AIDS.

2. The impact of HIV/AIDS on mortality

In the *2010 Revision*, countries where HIV prevalence among persons aged 15–49 was ever equal to or greater than two percent during 1980–2009, and/or the maximum effect of HIV/AIDS on life expectancy at birth was estimated to be greater or equal to two years are considered as affected by the HIV/AIDS epidemic and their mortality is projected by modelling explicitly the course of the epidemic and projecting the yearly incidence of HIV infection. Also considered among the affected countries are those where HIV prevalence is lower than one per cent but whose population is so large that the number of people living with HIV in 2009 is more than 700,000 (i.e., China, India, Russian Federation, United States). In total, 48 countries are considered to be most affected by the HIV/AIDS epidemic in the *2010 Revision*.

The model developed by the UNAIDS Reference Group on Estimates, Modelling and Projections^{14,15,16} is used to fit past estimates of HIV prevalence provided by UNAIDS for each of the affected countries so as to derive the parameters determining the past dynamics of the epidemic in each of them. For most countries, the model is fitted assuming that the relevant parameters have remained constant in the past. Beginning in 2009, the parameter PHI, which reflects the rate of recruitment of new individuals into the high-risk or susceptible group, is projected to decline by half every twenty years. The parameter R, which represents the force of infection, is projected to decline by half every thirty years. The reduction in R reflects the assumption that changes in behaviour among those subject to the risk of infection, along with increases in access to treatment for those infected, will reduce the chances of HIV transmission.

In the *2010 Revision*, interventions to prevent the mother-to-child transmission of HIV are modelled on the basis of estimated country-specific coverage levels that, in 2009, averaged 51 per cent among the 48 affected countries, but varied from 6 to 100 per cent among them (with 10 countries having less than 20 per cent coverage of pregnant women in 2009, and 14 countries with more than 75 per cent coverage). These coverage levels are projected to reach 74 per cent on average by 2015, varying between 40 per cent and 95 per cent among the affected countries.¹⁷ After 2015, the coverage of interventions to prevent mother-to-child transmission of HIV is assumed to remain constant until 2100 at the level reached in each of the affected countries in 2015. Among women receiving treatment, the probability of transmission from mother to child is assumed to vary between 2 per cent and 20 per cent depending on the particular combination of breastfeeding practices (mixed breastfeeding, replacement feeding, exclusive breastfeeding), its duration in the population and the type of treatment available (single-dose nevirapine, dual ARV prophylaxis, triple ARV prophylaxis or treatment). These assumptions produce a reduction in the incidence of HIV infection among children born to HIV-positive women, but the size of the reductions varies from country to country depending on the level of coverage that treatment reaches in each country.

The survivorship of infected children¹⁶ takes account of varying access to pediatric treatment.¹⁷ In the *2010 Revision*, HIV-infected children are divided into two groups: (i) those infected in-utero, among whom the disease progresses rapidly and whose median survival is set at 1.1 years, and (ii) those infected through breastfeeding after birth, among whom the disease progresses slowly and whose average survival is set at 9.4 years without treatment¹⁶. Explicit inclusion of pediatric treatment is done via country-specific coverage levels which average 33 per cent in 2009 but vary between 0 and 99 per cent among the 48 affected countries (with 8 countries having less than 10 per cent coverage in 2009 and only 7 countries having a coverage level above 75 per cent¹⁷). By 2015, the projected coverage is expected to reach 58 per cent on average in the 48 affected countries, varying from 40 per cent to 99 per cent. Coverage levels are assumed to remain constant from 2015 to 2100 at the level reached in each country by 2015. The annual survival of children receiving treatment is 85 per cent during the first year and 93 per cent for subsequent years.¹⁸

The *2010 Revision* incorporates a revised survival for persons receiving treatment with highly active antiretroviral therapy (ART).^{16,18} The proportion of the HIV-positive population receiving treatment in each country is consistent with estimates prepared by the World Health Organization¹⁹ and UNAIDS which averaged 64 per cent in 2009 among the 48 affected countries, but varied between 24 per cent and 100 per cent. Coverage is projected to reach between 40 per cent and 99 per cent by 2015, averaging 84 per cent for the affected countries. Between 2015 and 2050, coverage levels are assumed to remain constant at the level reached in each country by 2015. It is assumed that adults receiving treatment have, on average, an 86 per cent chance of surviving on the first year of treatment, and a 90 per cent chance of surviving each year thereafter in the absence of other causes of death. Under this assumption, mean survival time after the initiation of therapy is 9.1 years and the median survival time is 5.6 years, in the absence of other causes of death. Therapy is assumed to start at the time full-blown AIDS develops. Without treatment, infected adults have a mean survival time of 2.6 years (and a median survival time of 2.1 years) after the onset of full-blown AIDS.^{16,18}

3. Constant-mortality assumption

Under this assumption, mortality over the projection period is maintained constant for each country at the level estimated for 2005-2010.

C. INTERNATIONAL MIGRATION ASSUMPTIONS

1. Normal migration assumption

Under the normal migration assumption, the future path of international migration is set on the basis of past international migration estimates and consideration of the policy stance of each country with regard to future international migration flows. Projected levels of net migration are generally kept constant over the next decades. After 2050, it is assumed that net migration will gradually decline and reach zero by 2100.

2. Zero-migration assumption

Under this assumption, for each country, international migration is set to zero starting in 2010-2015.

D. EIGHT PROJECTION VARIANTS

The *2010 Revision* includes eight different projection variants (table V.1). Five of those variants differ among themselves only with respect to the level of fertility in each, that is, they share the assumptions made with respect to mortality and international migration. The five fertility variants are: low, medium, high, constant-fertility and instant-replacement fertility. A comparison of their results allows an assessment of the effects that different fertility paths have on other demographic parameters.

In addition to the five fertility variants, a constant-mortality variant, a zero-migration variant and a “no change” variant (i.e., both fertility and mortality are kept constant) have been prepared. The constant-mortality variant and the zero-migration variant both have the same fertility assumption (i.e., medium fertility).

October 2010, Volume 86, Supplement 2, pp. ii28-ii34; doi:10.1136/sti.2010.044255 - http://sti.bmj.com/content/86/Suppl_2.

¹⁹ WHO/UNAIDS/UNICEF. *Towards universal access: scaling up priority HIV/AIDS interventions in the health sector, progress report 2010*. Geneva, WHO, 2010. <http://www.who.int/hiv/en/>.

Furthermore, the constant-mortality variant has the same international migration assumption as the medium variant. Consequently, the results of the constant-mortality variant can be compared with those of the medium variant to assess the effect that changing mortality has on various population quantities. Similarly, the zero-migration variant differs from the medium variant only with respect to the underlying assumption regarding international migration. Therefore, the zero-migration variant allows an assessment of the effect that non-zero net migration has on various population quantities. Lastly, the “no change” variant has the same international migration as the medium variant but differs from the latter by having constant fertility and mortality. When compared to the medium variant, therefore, its results shed light on the effects that changing fertility and mortality have on the results obtained.

TABLE V.1. PROJECTION VARIANTS IN TERMS OF ASSUMPTIONS FOR FERTILITY, MORTALITY AND INTERNATIONAL MIGRATION

<i>Projection variant</i>	<i>Assumptions</i>		
	<i>Fertility</i>	<i>Mortality</i>	<i>International migration</i>
Low fertility	Low	Normal	Normal
Medium fertility	Medium	Normal	Normal
High fertility	High	Normal	Normal
Constant-fertility	Constant as of 2005-2010	Normal	Normal
Instant-replacement-fertility	Instant-replacement as of 2010-2015	Normal	Normal
Constant-mortality	Medium	Constant as of 2005-2010	Normal
No change	Constant as of 2005-2010	Constant as of 2005-2010	Normal
Zero-migration	Medium	Normal	Zero as of 2010-2015

E. METHODOLOGICAL CHANGES INTRODUCED IN THE 2010 REVISION

The following changes and adjustments were made in the *2010 Revision* in relation to procedures followed in the *2008 Revision*.

- The *2010 Revision* uses a new stochastic model for fertility projection as described above in section A.1 of Chapter V, and the medium fertility variant corresponds to the median of 100,000 projected country trajectories.
- The *2010 Revision* uses a long term stabilization level of 2.1 children per woman (which for many countries might only be reached by the end of the century or even later) rather than 1.85 children per woman as in previous revisions when the projection horizon was only up to 2050.
- With the extension of the projection horizon for all countries up to 2100 as part of the *2010 revision* of the *UN World Population Prospects*, it was necessary to allow life expectancy at birth to go beyond the limits of the standard model life table families (Coale and Demeny, 1966 and Coale and Guo, 1989 ; as well as United Nations, 1982) which are commonly used to derive a variety of mortality indicators and as underlying mortality patterns for estimation and projection. As part of the *2010 Revision* a new and extended version of Coale-Demeny and United Nations model life tables has been developed which extends the standard model life table families from 75 to 100 years of life expectancy at birth. This new version also insures greater consistency with the mortality experience of countries with the highest levels of life expectancy as recorded in the Human Mortality Database²⁰.

²⁰ For further details about the new extended models, see <http://esa.un.org/unpd/wpp/Model-Life-Tables/download-page.html> and for the methodology, see annex in Li, N. and P. Gerland (2011). "Modifying the Lee-Carter Method to Project Mortality Changes

- In the *2010 Revision*, the impact of HIV/AIDS on mortality is modelled explicitly for all countries where HIV prevalence among persons aged 15 to 49 was ever equal to or greater than two per cent between 1980 and 2009 in the general population, and/or the maximum effect of HIV/AIDS on life expectancy at birth is two or more years. Also considered among the affected countries are those where HIV prevalence is lower than one per cent but whose population is so large that the number of people living with HIV in 2009 is more than 700,000 (i.e., China, India, Russian Federation, United States).
- Both the survival time of HIV-positive children receiving treatment and the survival time of HIV-positive adults receiving treatment (after developing full-blown AIDS) decreased with respect to that used in the 2008 Revision (mean survival was revised down for children from 15.6 years to 11.6 and for adults from 17.4 years to 9.1). The revisions are consistent with recommendations of UNAIDS Reference Group on Estimates, Modelling and Projections (web site: <http://www.epidem.org>).

VI. ORDERING THE WORLD POPULATION PROSPECTS DATA ON CD-ROM OR DVD

The *2010 Revision of the World Population Prospects*, prepared by the United Nations Population Division, provides a comprehensive and consistent set of population data for the world's countries and their aggregates.

The results of this Revision are available on three CD-ROM or DVD editions that differ with regard to the data included and their prices (table 1). All three disks contain estimates and projections of national populations by five-year age group and sex for 1950-2100 and demographic indicators for the same period. Data for 1950-2010 are estimates and those thereafter are projections.

The Comprehensive CD-ROM contains for all fertility projection variants (low, medium, high and constant-fertility) all essential data such as total births, total deaths, total net-migration, the respective crude rates, life expectancy at birth by sex, infant and child mortality, summary measures of adult mortality and deaths by broad age groups, total fertility, net-reproduction rate and population growth rates for 1950-2100 by five-year periods. It includes population by five-year age group and sex for five-year periods and interpolated annual total population. In addition, this CD edition provides births and deaths by five-year age group, the corresponding age-specific fertility and mortality rates and abridged life tables (survivors and life expectancies at specific ages). It also comprises standard sets of demographic indicators and population by age group and sex for four other variants (instant-replacement-fertility, zero-migration, constant-mortality and no mortality and fertility change) and for two AIDS mortality scenarios. All data on this CD are presented in Excel worksheets and correspond to the datasets 1 to 3 and 5 to 12 listed in table 1.

The Extended DVD-ROM contains all the data from the Comprehensive CD, plus population figures by single calendar year and single age group for 1950-2100. This DVD also provides interpolated demographic indicators for single calendar years (total births and deaths, their respective crude rates, life expectancy at birth by sex, infant and child mortality, survivors to age 1, total fertility, etc.), urban population, population density and interpolated total population by broad age group and sex, and their respective percentage distributions and sex ratios. The data are presented in Excel and database formats (ASCII comma delimited format for all datasets) and correspond to all datasets listed in table 1.

The first two disks show data for 230 countries and areas, 35 country aggregates, including the world as a whole, the more and the less developed regions, and the major areas. For the AIDS scenarios (datasets 11-12), special aggregations by region and HIV prevalence level in 2009 are provided for 48 countries affected by the HIV/AIDS epidemic.

A new DVD-ROM for Special Aggregates contains a subset of indicators from the Extended dataset (only medium fertility variant), but instead of the breakdown by countries, data are aggregated for 276 functional groupings such as: 30 geographical regions (e.g., Central Asia, etc.), 54 economic and trading groups (e.g., World Bank regions and income groups, NAFTA, OPEC, OECD, G7, G20, BRIC, BRICS, ECOWAS, MERCOSUR, etc.), 32 political groups (e.g., NATO, G77, EU (15, 27, etc.), ASEAN, Arab League, African Union, GCC, SADC, SAARC, Sahel, Maghreb, Mashreq, etc.), 90 United Nations regional groups (e.g., UN Regional Commissions, MDGs, UNICEF, WHO, FAO, UNFPA, Non-Self Governing Territories), and 70 ecological groups (e.g., land-locked developing countries, small island developing states, countries with access to the sea, major international river basins, rainforest basins, extreme weather conditions, etc.).

The Microsoft Excel files correspond to version 97/2003 and later of this software. For a detailed listing of the contents of each disk, see table 2. Data files in database formats are shown in table 3.

For information on how to order any of these disks please see the order form at the end.

Dataset and File	Indicators	CD-ROM / DVD Edition ¹	Number of countries or areas	Projection variants or scenarios (starting in 2010)	Periods covered	Age groups
		SA	270	Medium-fertility only	2100	
F7.	Total population by broad age group and by sex	C/E SA	197 270	Low, medium, high, constant-fertility Medium-fertility only	1950, 1955,....2095, 2100	Total, 0-4, 0-14, 0-17, 0-19, 0-24, 5-14, 6-11, 12-14, 15+, 15-17, 15-24, 15-49, 15-59, 15-64, 18+, 18-23, 20+, 20-64, 20-69, 25+, 25-69, 50+, 60+, 65+, 70+, 75+, 80+, 85+, 90+, etc.
F8.	Percentage total population by broad age group and by sex	C/E SA	197 270	Low, medium, high, constant-fertility Medium-fertility only	1950, 1955,....2095, 2100	Total, 0-4, 0-14, 0-17, 0-19, 0-24, 5-14, 6-11, 12-14, 15+, 15-17, 15-24, 15-49, 15-59, 15-64, 18+, 18-23, 20+, 20-64, 20-69, 25+, 25-69, 50+, 60+, 65+, 70+, 75+, 80+, 85+, 90+, etc.
F9.1	Sex ratio by broad age group (males per 100 females by age group)	C/E SA	197 270	Low, medium, high, constant-fertility Medium-fertility only	1950, 1955,....2095, 2100	Total, 0-4, 0-14, 0-17, 0-19, 0-24, 5-14, 6-11, 12-14, 15+, 15-17, 15-24, 15-49, 15-59, 15-64, 18+, 18-23, 20+, 20-64, 20-69, 25+, 25-69, 50+, 60+, 65+, 70+, 75+, 80+, 85+, 90+, etc.
F9.2	Feminity ratio by broad age group (females per 100 males by age group)	C/E SA	197 270	Low, medium, high, constant-fertility Medium-fertility only	1950, 1955,....2095, 2100	Total, 0-4, 0-14, 0-17, 0-19, 0-24, 5-14, 6-11, 12-14, 15+, 15-17, 15-24, 15-49, 15-59, 15-64, 18+, 18-23, 20+, 20-64, 20-69, 25+, 25-69, 50+, 60+, 65+, 70+, 75+, 80+, 85+, 90+, etc.
F10.	Population density	C/E SA	230 270	Low, medium, high, constant-fertility Medium-fertility only	1950, 1955,....2095, 2100	---
Dataset 3. Population by age and sex, five-year periods						
F1.	Population by five-year age group (both sexes)	C/E SA	197 270	Low, medium, high, constant-fertility Medium-fertility only	1950, 1955,....1985, 1990	0-4, 5-9, ...75-79, 80+
					1995, 2000,....2095, 2100	0-4, 5-9, ...75-79, 80+, 80-84, ...95-99, 100+
F2.	Male population by five-year age group	C/E SA	197 270	Low, medium, high, constant-fertility Medium-fertility only	1950, 1955,....1985, 1990	0-4, 5-9, ...75-79, 80+
					1995, 2000,....2095, 2100	0-4, 5-9, ...75-79, 80+, 80-84, ...95-99, 100+
F3.	Female population by five-year age group	C/E SA	197 270	Low, medium, high, constant-fertility	1950, 1955,....1985, 1990	0-4, 5-9, ...75-79, 80+

TABLE 2. CONTENTS OF DATASETS IN DIGITAL FORM

Dataset and File	Indicators	CD-ROM / DVD Edition ¹	Number of countries or areas	Projection variants or scenarios (starting in 2010)	Periods covered	Age groups
				Medium-fertility only		
					1995, 2000,....2095, 2100	0-4, 5-9, ...75-79, 80+, 80-84, ...95-99, 100+
Dataset 4. Population by age and sex, annual (interpolated from five-year periods)						
F1A.	Population by five-year age group (both sexes)	E	197	Medium-fertility	1950, 1951,....1994	0-4, 5-9, ...75-79, 80+
F1B.	“	“	“	“	1995, 1996,....2100	0-4, 5-9, ...75-79, 80+, 80-84, ...95-99, 100+
F2A.	Population by five-year age group (male)	E	197	Medium-fertility	1950, 1951,....1994	0-4, 5-9, ...75-79, 80+
F2B.	“	“	“	“	1995, 1996,....2100	0-4, 5-9, ...75-79, 80+, 80-84, ...95-99, 100+
F3A.	Population by five-year age group (female)	E	197	Medium-fertility	1950, 1951,....1994	0-4, 5-9, ...75-79, 80+
F3B.	“	“	“	“	1995, 1996,....2100	0-4, 5-9, ...75-79, 80+, 80-84, ...95-99, 100+
Dataset 5. Mortality indicators by age and sex, five-year periods						
F1.	Deaths by five-year age group (both sexes)	C/E SA	197 270	Low, medium, high, constant-fertility Medium-fertility only	1995-2000,....2095-2100	0-4, 5-9,....75-79, 80+
F2.	Deaths by five-year age group (male)	C/E SA	197 270	Low, medium, high, constant-fertility Medium-fertility only	1995-2000,....2095-2100	0-4, 5-9,....75-79, 80+
F3.	Deaths by five-year age group (female)	C/E SA	197 270	Low, medium, high, constant-fertility Medium-fertility only	1995-2000,....2095-2100	0-4, 5-9,....75-79, 80+
F4.	Life table l(x) values by sex	C/E SA	197 270	Medium-fertility	1995-2000,....2095-2100	0, 1, 5, 10,....80, 85
F5.	Life expectancy at age (x) by sex	C/E SA	197 270	Medium-fertility	1995-2000,....2095-2100	0, 1, 5, 10,....95, 100
Dataset 6. Fertility indicators by age, five-year periods						
F1.	Births by five-year age group of mother	C/E SA	197 270	Low, medium, high, constant-fertility Medium-fertility only	1995-2000,....2095-2100	15-19, 20-24,....45-49
F2.	Age-specific fertility rates	C/E SA	197 270	Low, medium, high, constant-fertility Medium-fertility only	1995-2000,....2095-2100	15-19, 20-24,....45-49

F5.	Population by single age (female)	E	197 270	Medium-fertility	1950, 1951,.....1994	0, 1, 2,... 79, 80+
					1995, 1996,.....2100	0, 1, 2,... 79, 80+, 81... 99, 100+

Note: (1) CD-ROM or DVD editions are: C = Comprehensive (CD-ROM), E = Extended (DVD), SA = Special Aggregates (DVD)

Datasets 11 to 12 present, in addition to the default AIDS mortality scenario (medium), three other AIDS scenarios for 48 countries affected by the HIV/AIDS epidemic: the No-AIDS scenario applies the mortality likely to be exhibited by the non-infected population to the whole population, thus excluding the direct impacts of the epidemic. The estimates associated with the No-AIDS scenario (that is, the figures for 1980-2010) differ from the estimates of the other variants because AIDS started affecting the populations in the majority of the highly-affected countries around 1980. By comparing these results with those of the estimates and medium variant that include explicitly the effects of the HIV/AIDS epidemic, the user can infer the impact of the epidemic.

TABLE 3. DATA FILES IN DATABASE FORMAT INCLUDED IN THE EXTENDED DVD EDITION
(similar structure for Special Aggregates DVD but different set of records and only for medium fertility variant)

Topic / Data file	Description	Data file format ¹	Number of indicators ²	Number of records
WPP2010_F01_Locations.csv and .dat file with Stata/SPSS/SAS dictionary	Location list with codes (numerical and ISO3), description, major area, region and development group; countries with explicit HIV/AIDS mortality modelling in WPP 2010 revision, HIV prevalence rate (%) in population aged 15-49 years in 2009 (UNAIDS, 2010) and by prevalence group, peak of HIV epidemic (year and value for maximum prevalence between 1980-2009), comparison for 2007 HIV prevalence rate between UNAIDS 2008 and 2010 revisions.	CSV & DAT	29	279
WPP2010_F02_MetaInfo.csv and .dat file with Stata/SPSS/SAS dictionary	Latest data sources (summary, type of data and reference date) used to derive estimates for total population, fertility, mortality and migrations by countries or areas (includes information about method used to derive mortality estimates, age mortality pattern and child mortality).	CSV & DAT	43	279
DB01. Period indicators				
WPP2010_DB01_Period_Indicators.csv and .dat file with Stata/SPSS/SAS dictionary	All period indicators (total fertility, net reproduction rate, crude birth rate, births, mean age of childbearing, life expectancy at birth (by sex), infant mortality rate, under-five mortality, crude death rate, total number of deaths (by sex) and by broad age group, percentage total deaths by broad age group and by sex, probability of dying between birth and the age of 40 or 60 years (by sex), adult probability of dying between age 15 and 50 or 60 (by sex), life expectancy at age 15, 60 and 80 (by sex), net migration rate, net number of migrants, average annual rate of population change,	CSV & DAT	172	66,847
